

A brief introduction to ISO 28005-1

Ørnulf Jan Rødseth, Director Maritime ITS, ITS Norway

API versus electronic document exchange

Electronic document exchange

Application programming interface
API = Protocol + Message structure + Data

REST API: Representational state transfer API

Protocol: HTTP

Message structure + Data: HTTP defined

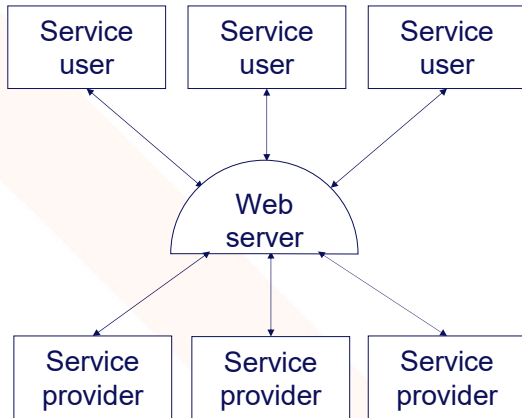

Specific rules for how HTTP is used

Note: HTTP is a protocol that is used, e.g. for web browsers. HTTPS (secure HTTP) is the commonly used variant, but the protocol definition is still HTTP.

REST APIs are much used for «microservices» architectures.

REST is not used by ISO 28005

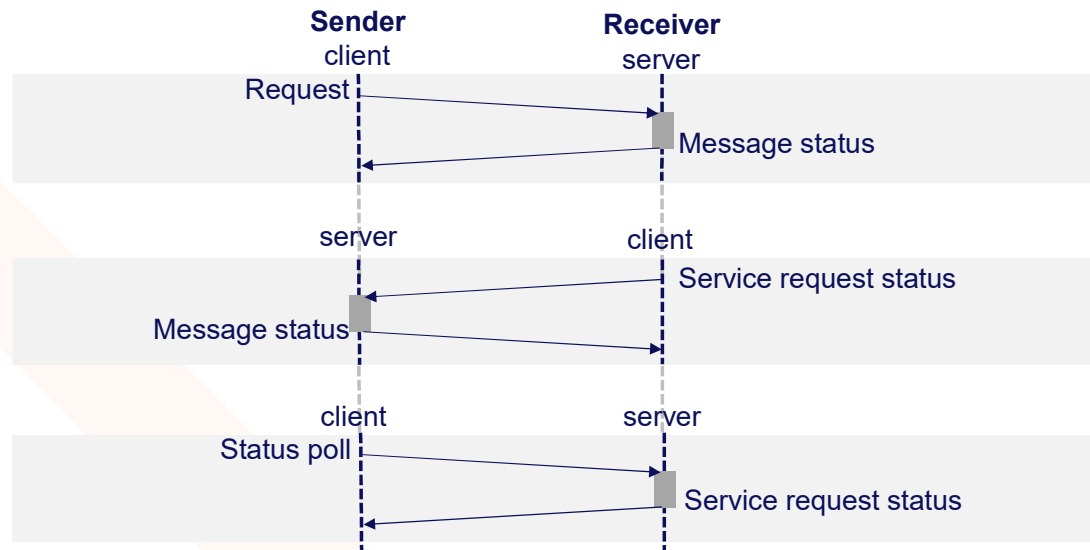

ISO 28005 physical services architecture.

Example of REST «microservices» architecture.

Sender/Receiver versus client/server

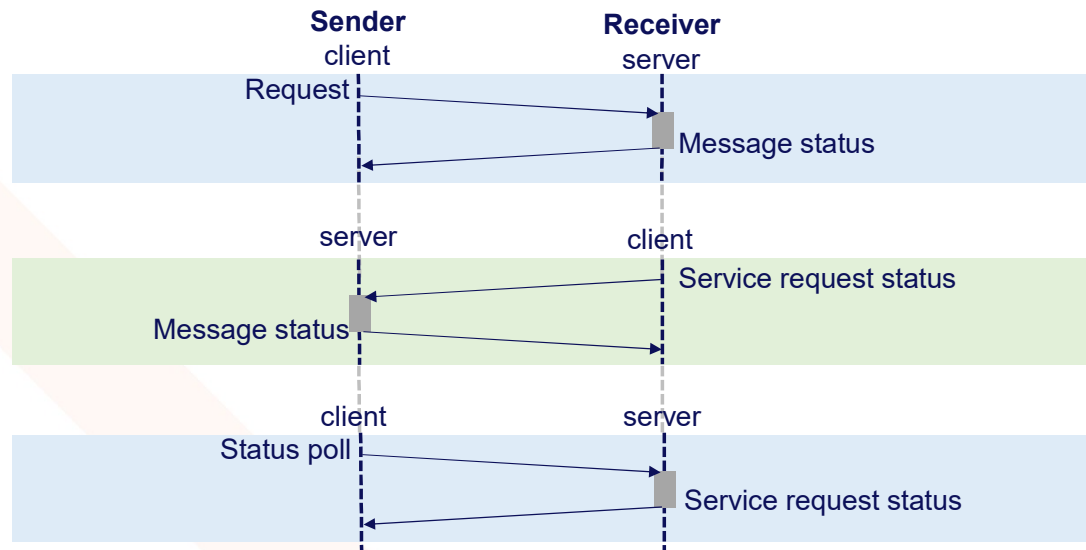

Sender:

Party that requests a service from a receiver.

Receiver:

Party that receives requests and provides services.

Sender/Receiver versus client/server

Sender:

Party that requests a service from a receiver.

Receiver:

Party that receives requests and provides services.

Asynchronous:

Sender can be both server and client.

Synchronous:

Sender can only be client. Uses polling of receiver to check status.

API versus API Access Point as used by ISO 28005

API Access Point:

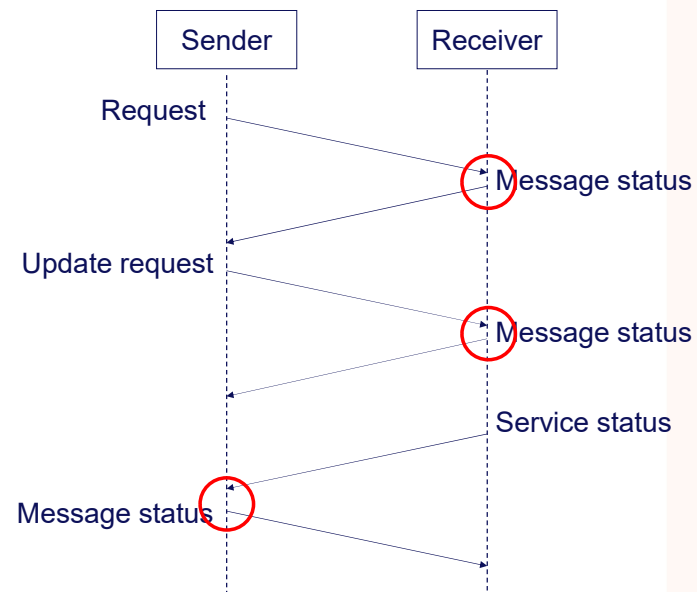

Protocol: Standardized (HTTP)

Message structure: Standardized, flexible

Each API:

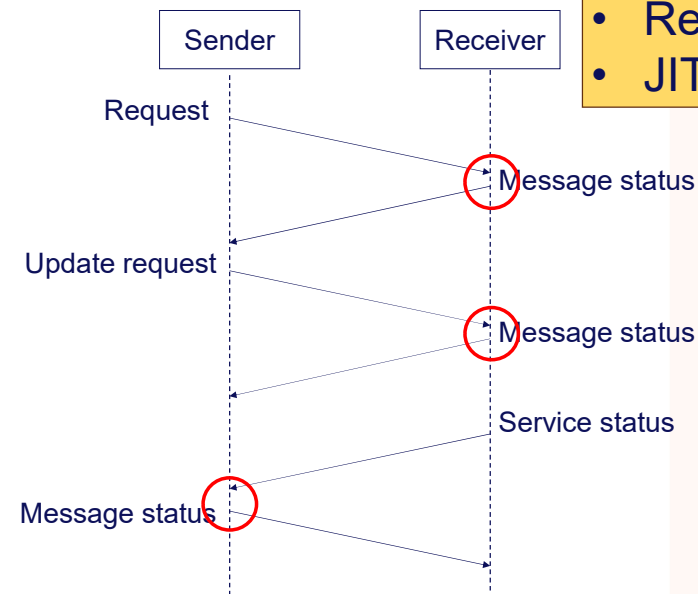

Use standard API Access point

Different data in flexible message

API = Protocol + Message structure + Data

API = Protocol + Message structure + Data

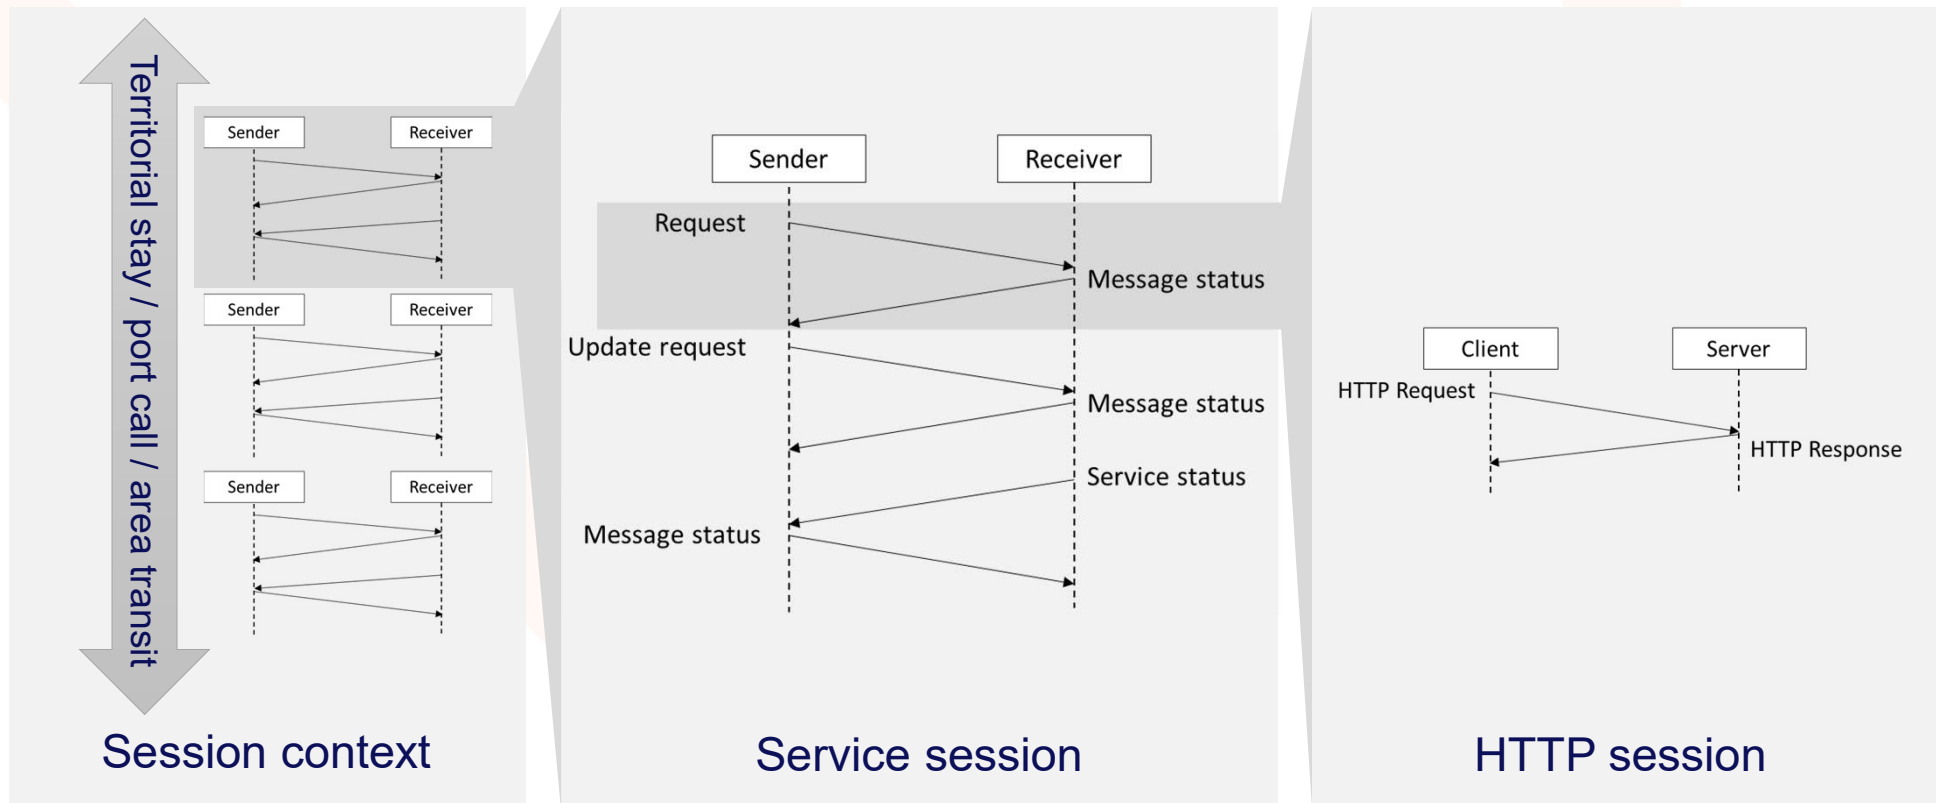

Example services:

- Send one document
- Order tugs
- Request terminal berth
- JIT negotiation

Several coordinated APIs may be needed to request «services»
For set of coordinated APIs, we also need «choreography»

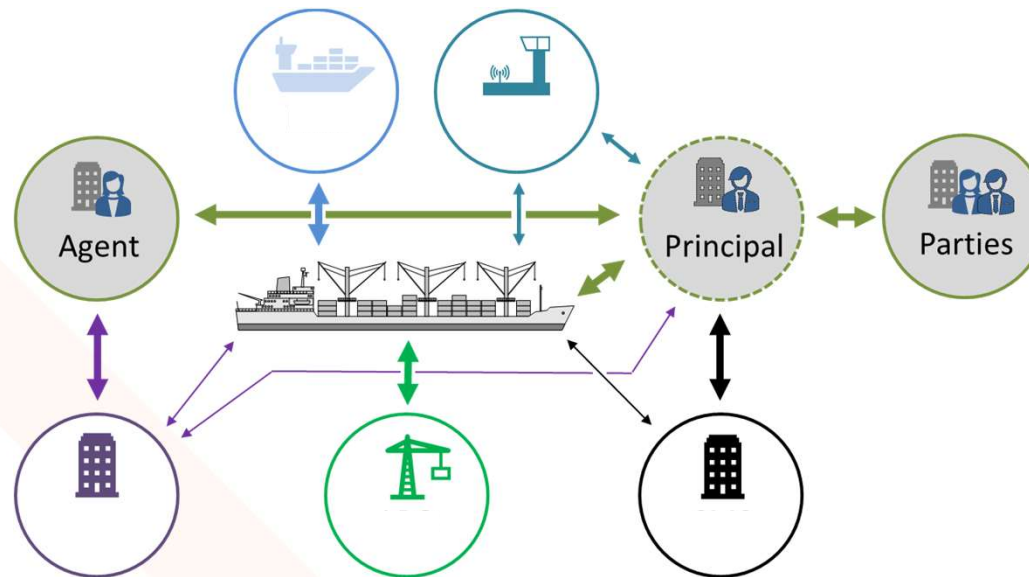

Coordinated APIs need a session concept

ISO 28005 is transport independent, but includes HTTPS as standard

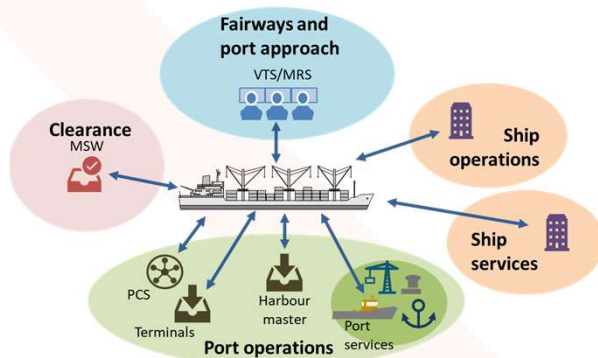

ISO 28005 is transport independent, but includes HTTPS as standard

Also useful if ship uses shore based principal (owner, manager or charterer) to communicate with other parties.

ISO 28005 is a peer-to-peer API access point specification

Ship-centric
ship-shore operational
and administrative
communication.

Technical specification enabling
consistent development of APIs
for peer-to-peer
communication.

No public key infrastructure, no
service discovery, no user
registry. This can be
implemented as a service.

Flexible multi-part message structure

Message header:

Connection management and for determining service. Always XML.

Message body:

API specific data content. May also be in other formats than XML.

Attachments:

Data sheets, photos, encrypted content etc. Any format.

Message header (XML)		} Message header Always one
Sender identity	Receiver identity	
Message reference	Service name	
Acknowledgement method	Service request reference	
Sent time	Service request type ...	
Message body (XML, JSON, EDIFACT ...)		} Add for data content Zero or one
Data required to implement the requested service as defined in other parts of ISO 28005.		
Attachments (PDF, PNG, JPG, XML ...)		} Attachments Zero or more
Attachments referenced in the message body or header		
X.509 certificates (PEM)		} Public key certificates Zero or more
X.509 certificate for signatories		
Digital signature (XML)		} Digital signatures Zero or one
Authentication, Integrity, Non-repudiation ...		

Flexible multi-part message structure

```
Content-Type: multipart/form-data; boundary="r4nd0m"
Content-Encoding: gzip

Prose text: This is an electronic message in the ISO 28005-1 format.
The attachments contain the different parts of the message.

--r4nd0m
Content-Type: application/xml; charset=utf-8
Content-Disposition: form-data; name=header;

[XML header goes here]
--r4nd0m
Content-Type: application/xml; charset=utf-8
Content-Disposition: form-data; name=body;

[XML body goes here - zero or one of this block]
--r4nd0m
Content-Type: application/pdf
Content-Disposition: form-data; name=attach1; filename=file1.xxx;

[attachment data goes here - zero or more of these blocks]
--r4nd0m
Content-Type: application/pkix-cert;
Content-Disposition: form-data; name=cert1; filename=cert1.cer;

[A DER encoded X.509 certificate goes here - zero or more]
--r4nd0m
Content-Type: application/xml; charset=utf-8
Content-Disposition: form-data; name=signature;

[XML signature goes here - zero or one of this block]
--r4nd0m--
```

Multipart/form-data:
Standard HTTP construct for
messages with more than one part,
possibly in different formats.

Message header

Sender information (from sender)

- Sender and ship identity, request reply method, authorization code

Receiver information (from receiver)

- System identity (MSW, PCS, etc.), receiver identity

Message information (used by both)

- Sent and created times, message reference codes, manifest and part types

Service request information (mainly from sender)

- Service description, reference codes, session context

Message and service status (from receiver)

- Status codes, missing data items, error message for humans

Message header (XML)		} Message header Always one
Sender identity	Receiver identity	
Message reference	Service name	} Add for data content Zero or one
Acknowledgement method	Service request reference	
Sent time	Service request type ...	
Message body (XML, JSON, EDIFACT ...)		} Attachments Zero or more
Data required to implement the requested service as defined in other parts of ISO 28005.		
Attachments (PDF, PNG, JPG, XML ...)		} Public key certificates Zero or more
Attachments referenced in the message body or header		
X.509 certificates (PEM)		} Digital signatures Zero or one
X.509 certificate for signatories		
Digital signature (XML)		
Authentication, Integrity, Non-repudiation ...		

Message body

Standard XML format

- Contains all defined data objects as optional. API defines what elements should be used.

Option EDIFACT

- Useful for complex cargo manifests and long passenger lists.

Option ISO 19848 (XML or JSON)

- Useful for technical data from ship (e.g. fuel consumption reports).

Option JSON

- Generic, no specific application has been defined.
- ISO 28005 message body XML format easy to translate to JSON if desired.

Message header (XML)		} Message header Always one
Sender identity	Receiver identity	
Message reference	Service name	} Add for data content Zero or one
Acknowledgement method	Service request reference	
Sent time	Service request type ...	
Data required to implement the requested service as defined in other parts of ISO 28005.		
Attachments (PDF, PNG, JPG, XML ...)		} Attachments Zero or more
Attachments referenced in the message body or header		
X.509 certificates (PEM)		} Public key certificates Zero or more
X.509 certificate for signatories		
Digital signature (XML)		} Digital signatures Zero or one
Authentication, Integrity, Non-repudiation ...		

Message attachments

Data sheets for dangerous cargo

- Typical PDF-file, sometimes required.

Pictures

- Required, e.g. for stowaways.

Encrypted message body parts

- May be required for personal information when transmitted through 3rd party systems (PCS).
- Examples are passenger and crew lists, health declaration, stowaway reports.

Other formats

- May also contain, e.g. EDIFACT parts of a message body.

Message header (XML)		} Message header Always one
Sender identity	Receiver identity	
Message reference	Service name	
Acknowledgement method	Service request reference	
Sent time	Service request type ...	
Message body (XML, JSON, EDIFACT ...)		} Add for data content Zero or one
Data required to implement the requested service as defined in other parts of ISO 28005.		
Attachments (PDF, PNG, JPG, XML ...)		} Attachments Zero or more
Attachments referenced in the message body or header		
X.509 certificates (PEM)		} Public key certificates Zero or more
X.509 certificate for signatories		
Digital signature (XML)		} Digital signatures Zero or one
Authentication, Integrity, Non-repudiation ...		

Security

Use HTTPS to avoid eavesdropping.

Allow synchronous operation to allow only outgoing connections from ships.

Use digital signatures for authentication and message integrity.

Use acknowledgements and digital signatures for non-repudiation.

Implementation

Not using REST

- HTTP layer is not integrated in ISO 28005 processing.
- Can use off-the-shelf HTTP-libraries.
- Easy to use other data transport layers.

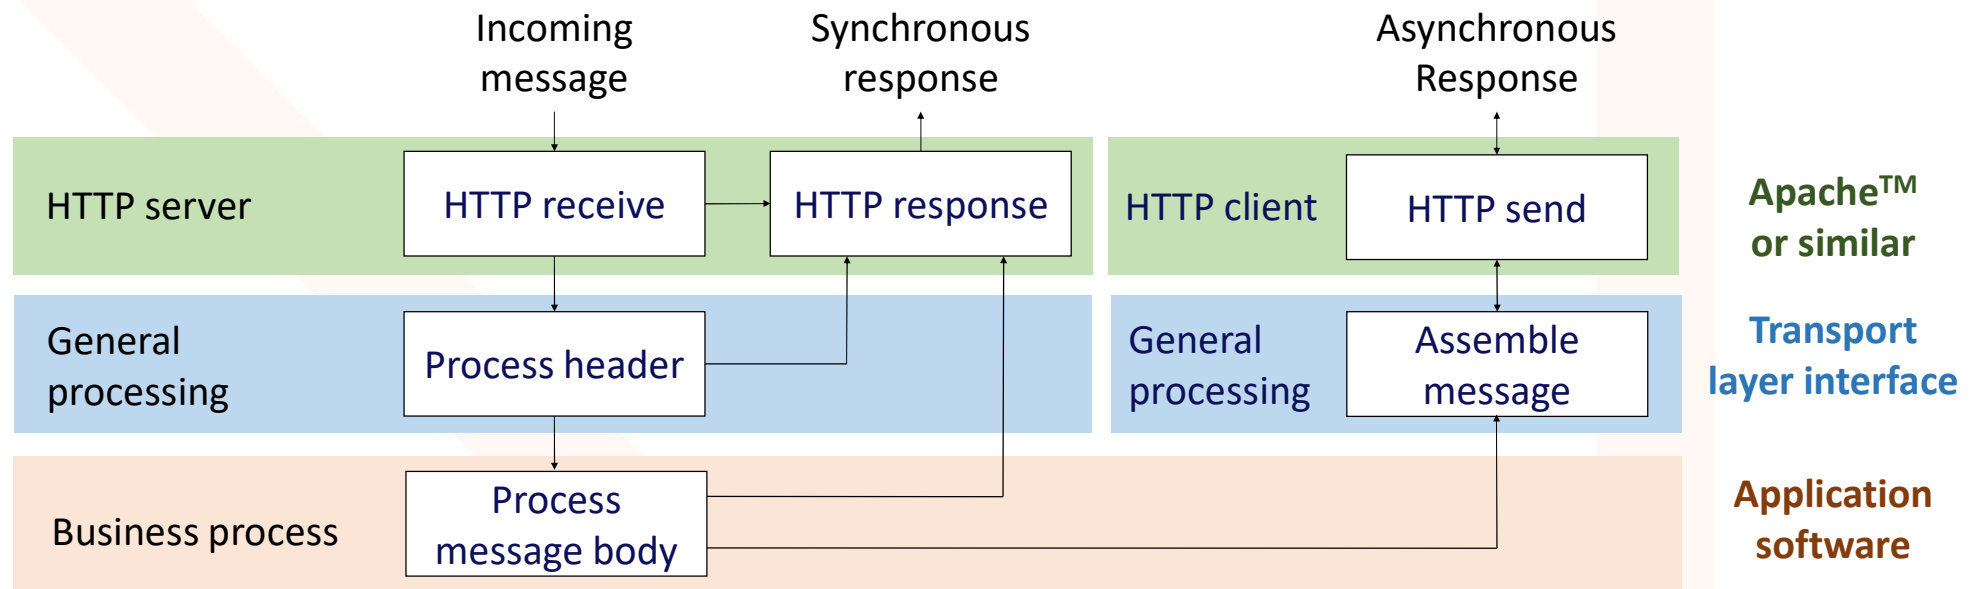

Standard HTTP and XML constructs

- Good availability of libraries and tools.

Allows simplified processing

- Do not need to implement complex API choreography if not needed.
- Allowed to define minimum data sets for body and header.

ISO 28005 enables a modular software structure
